How to do conformance checking in ProM

Josep Carmona Boudewijn van Dongen Matthias Weidlich Andreas Solti

This tutorial provides a step-by-step manual for conformance checking in ProM, using data from the BPI challenge 2012 as well as some models for that data. The theoretical background is provided by the book "Conformance Checking", available through Springer.

The ProM toolkit can be downloaded from <u>www.promtools.org</u>. This tutorial uses ProM Lite, but all versions of ProM can be used for conformance checking as long as the package "Alignment" is installed in the package manager.

Starting ProM

After launching ProM, the main screen is shown.

Opening files

Files can be loaded by clicked on the *Import* button, which is highlighted through a red box in the figure above. In the laboratory session, we use data from the BPI Challenge 2012 (<u>https://data.4tu.nl/repository/uuid:3926db30-f712-4394-aebc-75976070e91f</u>) and models provided through Canvas

There are three models for this dataset, namely a model for "A_" activities, a model for the "O_" activities and a model for the "AO_" activities. Therefore, the first step in conformance checking is to filter the event log to keep only those activities that are relevant for the model under consideration.

In the tutorial, we focus on the "AO_" model, which looks like this:

All three models are man-made, i.e. they are not the result of a mining algorithm The models have properties like duplicate transitions (transitions with identical labels) and routing transitions (transitions that are black and cannot be observed).

A correct execution of the model starts with a token in the initially marked place and ends with one token in the final place. The question for conformance checking is: What is the relation between the behaviour in the log and the behaviour described in the model.

Filtering the log

For filtering, we use the simple heuristics filter which is contained in a plugin called "Filter Log using Simple Heuristics".

ProM	6		•		designed by	fluxicon
Actions						0

N. C.		Plugin action info				
Filter Log Package: L Author: <u>HMW</u> Categories: F	using Simple Heuristics .og <u>W Verbeek</u> -iltering					1

After starting this plugin, you get a wizard that guides you through the filtering steps. To only keep the activities that start with "A_" or "O_" and only complete cases, we need to perform filtering as follows:

 Keep all lifecycle types and change the names accordingly.

START COMPLETE SCHEDULE			(keep) (keep) (keep)	
COMPLETE SCHEDULE			(keep) (keep)	
SCHEDULE				
lange 2012 (AO complete)			_	
tenge zo iz (Ao complete)				
				Next
	ienge 2012 (AO complete)	lenge 2012 (AO complete)	ienge 2012 (AO complete)	ienge 2012 (AO complete)

2) Keep all start events

3) For now, keep all end events

 Finally, keep all events that start with "A_" or with "O_"

Conformance Checking

After selecting both a log and a model, select the "Replay a log on Petri net for Conformance Analysis" plugin.

Conformance setup

If no final marking is known for the model yet, you will be asked to provide one.

For our model, we need

the model to

terminate in the marking [p_final] and that is what we specify in the following dialog:

Select mapping	
List of Places	Candidate Final Marking
p1 p2 p3 p4 p6 p7 p8 p9 p10 p_cancelled p_declined p_final p_oaccept p_odecline pa1 pa2 pa3 pa4 pa5	Add Place >>
Cancel	Previous Finish

In the next step, we need to link labels of events in the log to labels of transitions in the model. By default, ProM will suggest to use the "MXML Legacy Classifier" which for this log is not the right choice. Instead, we select the "Event Name" classifier.

Mapping Petrinet - Event Class of Log				
Map Transitions to Event Classes First, select an appropriate classifier. Unmapped transitions will be mapped to a dummy event class. Approximate matches are highlighted in yellow and should be carefully reviewed.				
Choose classifier	Event Name			
Use approximate matching	Use Approximate Matches			
A_ACCEPTED A_ACTIVATED	A_ACCEPTED A_ACTIVATED			
A_APPROVED	A_APPROVED			
A_CANCELLED_1 A_CANCELLED_2	A_CANCELLED			
A_CANCELLED_3	A_CANCELLED			
A_DECLINED_1	A_DECLINED			
A_DECLINED_3	A_DECLINED			
A_DECLINED_4	A_DECLINED			
A_FINALIZED A_PARTLYSUBMITTED	A_FINALIZED			
Cancel	Previous Finish			

The tool then proposes a mapping based on string similarity. Labels that match fully are shown in grey. Labels that do not match fully are shown in yellow and these should manually be checked. In our case, the automatic mapping is correct and we can click "Finish"

Conformance Checking

After setting up the model with an initial and final marking as well as the mapping between the log and the model, we continue with conformance checking.

ProM contains many techniques, but the default suffices for this tutorial:

In the next screen, we can set the costs of deviations.

Replay in Petri net			
Set parameters Double click costs on table to change their values. Us	e only non-negative integers.		
# Maximum explored states (in hundreds). Set	max for unlimited.	ove on Model Cost	
A_ACCEPTED A_ACTIVATED A_APPROVED A_CANCELLED_1 A_CANCELLED_2 A_CANCELLED_3 A_DECLINED_1 A_DECLINED_3 A_DECLINED_3 A_DECLINED_3	1 1 1 1 1 1 1 1		l
Set all c	osts above to 1	et	
Event Class		Move on Log Cost	
A_ACCEPTED A_ACTIVATED A_APPROVED A_CANCELLED A_DECLINED A_FINALIZED A_PARTLYSUBMITTED A_PREACCEPTED A_REGISTERED	1 1 1 1 1 1 1 1		
Cancel		Previous Finish	

Again, the default cost function suffices and after clicking the analysis starts. The resulting screen is a model with colors indicating the deviations:

The darker blue the fill is, the more frequent an activity in the log. The bottom of each transition shows green/purple bar indicating the fraction of correct/incorrect executions. Places that are coloured yellow indicate that there was an event in the log that could not be explained when there was a token in that place.

What is striking in this picture is the large amount of purple bars in the "O_SENT_BACK" transition. Apparently, these transitions are often necessary to explain a trace in the log, while they did not appear in the log, i.e. they appear to have been skipped during execution of the process.

At this stage, it's up to you to contact the process owner and the check if this is the case and if so, why?

The explanation here is that the computer system used only allows for one offer to be created for each application, while customers prefer

to receive multiple offers to choose from. Call agents therefore create an offer, print it and cancel it without the offer ever leaving the bank, nor being sent back. After that the call agent create a new offer, print it and send two offers in one envelope to the customer. If then a signed offer is received back and it happens to be the first offer created, then this loop is repeated again to re-create the first offer.

A clear example of human call agents working around the intended behaviour.

A more interesting problem is the fact that the transition "O_ACCEPTED" appears to be skipped frequently. It is listed as being skipped 403 times out of 2,246 cases. This would imply that for 2,246 cases an offer was not accepted, but a loan was approved and activated (money payed to the customer).

Dealing with time

Unfortunately, the event log has a property that many logs have. Multiple events have the same time stamp, i.e. according to the log, they occurred at the exact same time and hence, in the log, the ordering of these events is arbitrary. As the ordering in the model is enforced by the places, this leads to false deviations.

To resolve this, do the replay again, but this time in the dialog where you can set the costs of deviation, select the option to treat events with the same timestamps as partially ordered events.

	Set all costs above to O Set
	Treat events with same timestamps as partially ordered events
/	Cancel Previous

The result is a model with fewer deviations:

DECLINED_3

The deviations around "O_SENT_BACK" are still there, as expected. However, now, there appear to be only three cases where "O_ACCEPTED" was skipped out of 2,246.

Filter based on deviations

Using the filter dialog, we filter the log to keep only those cases in which this activity "O_ACCEPTED" was skipped.

For this, we use the "Movement Containment Filter" in the inspector panel and we filter out all cases without the move on model "O_ACCEPTED". (to do this, uncheck "O_ACCEPTED" in the middle list, then click inverse and then "Filter...")

The result should now show:

After filtering, we can export the log using the export tab in the inspector panel.

After exporting and giving the log an appropriate name, you obtain a log with 3 cases and 45 events.

Inspecto	r		<u> </u>
Info	Display	Filter	Export
Export			
Expor	t graph as im	age	
Expor	t shown case	es as new l	Log

Using the log inspector, you can manually verify that indeed, for cases 177083, 180310 and 198310, no offer was accepted, while the loans were activated, i.e. money was transferred to the client. A total of 18,000+20,000+25,000 = 63,000 euro.

This is a clear compliance violation.

Final Notes

ProM is an academic prototype. The authors have made huge efforts in making this tool accessible and functional for a large number of use cases. If you find bugs, please report them during the lectures or on the ProM Forum, but don't expect immediate fixes.

About the files

The log used was provided by a company for the BPI Challenge 2012. This challenge is organized yearly by the process mining research group in Eindhoven and challenges participants from all over the world to show their process mining abilities.

Currently known bugs/issues:

High resolution screens: The chart area cannot scale beyond a certain resolution. Beyond 2560x1440, the fonts get stretched and the location of the tooltip doesn't match the actual events. This a Java issue and can, at this point, not be circumvented.

Workaround 1: On high resolution screens, keep the ProM window smaller than 2560x1440 physical pixels.

Workaround 2: select the ProMLite12.exe file, go to properties and under compatibility, select "Override high DPI scaling behavior. Scaling performed by System". Note that this only works if the scaling is such that the scaled screen has a resolution less than 2560x1400. For a 4K screen, this is 150% scaling.
